#labs(...) # for the main title, axis labels and legend titles
```

As the above plots show, it's clear that the distributions are skewed to the right which means that expensive schools are generally less common. It's interesting to see that both of these seem to have similar shapes, and a hint of evidence for a slight bimodal distribution.

```
ggplot(gatheredtc, aes(x=totalCost,fill=in_out))+geom_histogram(bins=75)+expand_limits(x=80000) +
  ggtitle("Total cost of attendance for students by residence")+ # for the main title
  xlab("Cost of attendance")+ # for the x axis label
  ylab("Count") + # for the y axis label
  theme_bw()+theme(
    legend.title = element_blank(),
    ) + scale_fill_discrete(name = "Student Residence", labels = c("In-state", "Out-of-state"))
```

Total cost of attendance for students by residence
Upon further inspection by increasing the bin number, the shape becomes more distinct. The second mode is mostly just a bump for the out-of-state group, but something interesting appears in the in-state group! Is there a cause for this disruption?

```
tcInStateSummr = tcFactored %>%
  group_by(degFactor) %>%
  summarize(median(in_state_total))

tcOutStateSummr = tcFactored %>%
  group_by(degFactor) %>%
  summarize(median(out_of_state_total))

tcInStateSummr
```

```
## # A tibble: 3 x 2
##   degFactor `median(in_state_total)`
##   <fct>                        <dbl>
## 1 2 Year                       4972.
## 2 4 Year                      28287
## 3 Other                        8448
```

```
tcOutStateSummr
```

```
## # A tibble: 3 x 2
##   degFactor `median(out_of_state_total)`
##   <fct>                            <dbl>
## 1 2 Year                           10291
## 2 4 Year                           34888
## 3 Other                            14640
```

This is a simple calculation of the median for 2-year and 4-year schools for total cost to out-of-state students.

```
tcFours = tcFactored %>%
  filter(degFactor=="4 Year")
tcFours
```

```

```
These are the 5-number summaries for each of the categorical variables of interest.
```
ggplot(tcFactored, aes(x = degFactor, y = in_state_total)) +  # ggplot function
  geom_boxplot()
```

```
ggplot(tcFactored, aes(x = degFactor, y = out_of_state_total)) +  # ggplot function
  geom_boxplot()
```

These box plots (couldn't figure out how to make an overlayed boxplot with both in/out of state variables) show a clear difference in the general cost between 2-year and 4-year institutions, and that out-of-state students generally pay more.

```
#ggplot(tcFactored, aes(x=tcInStateSummr$degFactor, fill=tcInStateSummr$in_state_total)) +
#  geom_histogram( color="#e9ecef", alpha=0.6, position = 'identity') +
#  scale_fill_manual(values=c("#69b3a2", "#404080"))
```

```
ggplot(gatheredtc, aes(x = degFactor, y = totalCost, fill=in_out)) +  # ggplot function
  geom_boxplot()+
  ggtitle("Breakdown of total cost of attendence by degree factor")+ # for the main title
  xlab("Degree Factor (2/4 year)")+ # for the x axis label
  ylab("Cost of Attendance")+ # for the y axis label
  theme_bw()+theme(
    legend.title = element_blank(),
    ) + scale_fill_discrete(name = "Student Residence", labels = c("In-state", "Out-of-state"))
```

Breakdown of total cost of attendence by degree factor
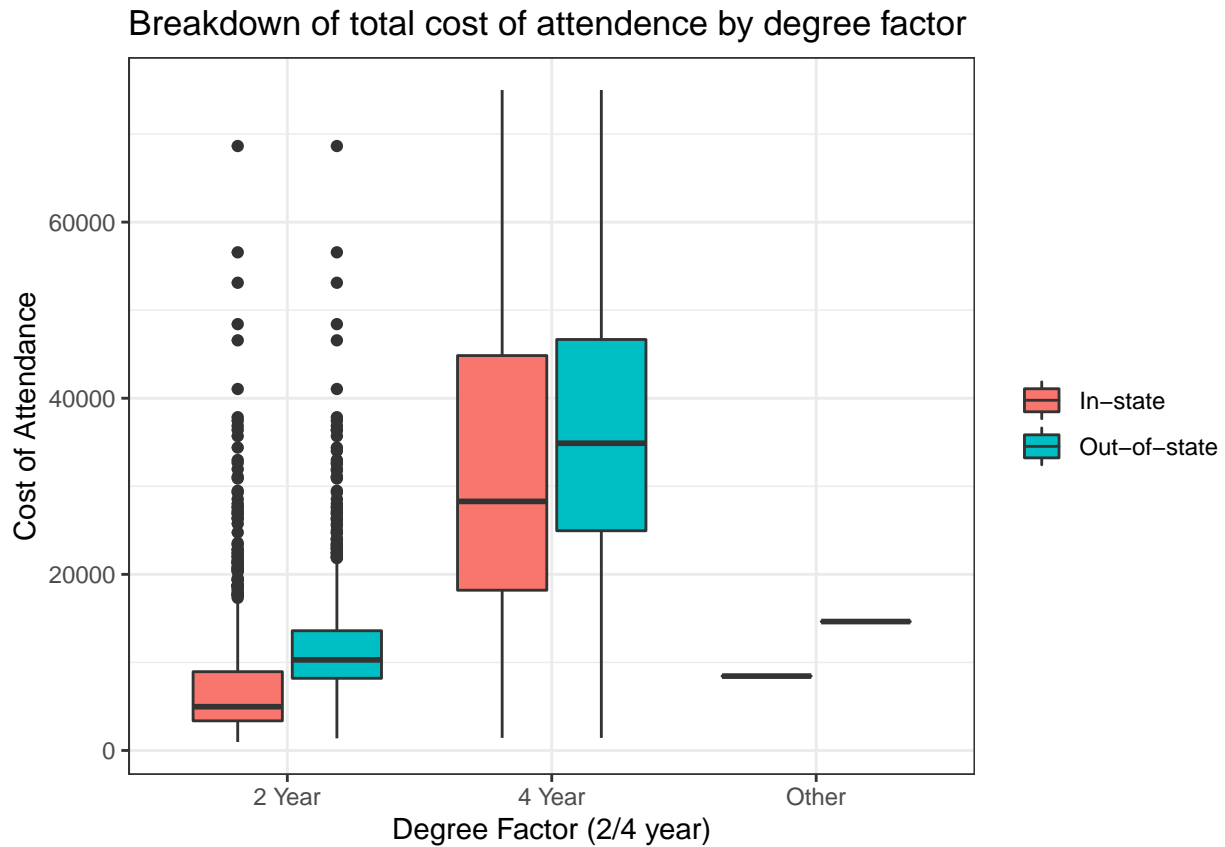

There is clearly a difference here between how much students should expect to pay given their residency status, but it isn't as absurdly significant as we were anticipating given that we hear from high school guidence counselors, specifically about 4-year institutions. Therefore, we should look for another potential explanation for the contribution to higher costs of attendance for some students.
